

REMARKS

By this Amendment, claims 1-3 are cancelled, and claims 4-6 are added. Thus, claims 4-6 are active in the application. Reexamination and reconsideration of the application are respectfully requested.

The specification and abstract have been carefully reviewed and revised in order to correct grammatical and idiomatic errors in order to aid the Examiner in further consideration of the application. The amendments to the specification and abstract are incorporated in the attached substitute specification and abstract. No new matter has been added.

Also attached hereto is a marked-up version of the substitute specification and abstract illustrating the changes made to the original specification and abstract.

In item 5 on page 2 of the Office Action, claims 1-3 were objected to because of the informalities identified at the top of page 3 of the Office Action. This objection is believed to be moot in view of the cancellation of claims 1-3. Furthermore, the Applicants respectfully submit that new claims 4-6, which have been added in favor of cancelled claims 1-3, respectively, have each been drafted to include the amendments kindly suggested by the Examiner. Accordingly, the Applicants respectfully request that the objection to the claims be withdrawn.

In item 7 on page 3 of the Office Action, claims 1-3 were rejected under 35 U.S.C. § 102(a) as being anticipated by Kazuyuki et al. (JP 2002-075208, hereinafter "Kazuyuki"). This rejection is believed to be moot in view of the cancellation of claims 1-3. Furthermore, the Applicants respectfully submit that this rejection is inapplicable to new claims 4-6 for the following reasons.

Performing an aging process, as conventionally known in the art, thins the surface of a protecting layer that covers a dielectric layer, which covers a display electrode that is formed of a pair of a scan electrode and a sustain electrode. Excessively strong aging provides the surface of the protecting layer with excessive sputtering and thereby shortens the life of the plasma display panel.

The present invention, as recited in new claims 4-6, provides a plasma display panel which is configured in such a manner that a small discharge dent is formed in aging, and therefore, the present invention offers an advantage of providing a long-life

plasma display panel. These features of the present invention are achieved by the inventions of new claims 4-6.

New claims 4 and 5 each recite a plasma display panel comprising a display electrode formed of a pair of a scan electrode and a sustain electrode, a dielectric layer disposed so as to cover the display electrode, and a protecting layer formed on the dielectric layer.

New claim 4 recites that an aging discharge is performed in the plasma display panel by applying a voltage having an alternate voltage component at least between the scan electrode and the sustain electrode. Furthermore, new claim 4 recites that, in the plasma display panel, a discharge dent on the protecting layer on the side of the sustain electrode, which is formed by the aging discharge, has a width which is narrower than a discharge dent on the protecting layer on the side of the scan electrode.

In rejecting claim 1, the Examiner opined that because Figures 1 and 3-4 of Kazuyuki allegedly disclose the structural elements of the plasma display panel of claim 1, “the recited result ‘the discharge dent on the side of the sustain electrode has a width narrower than the discharge dent on the side of the scan electrode’ would necessarily be inherent in Kazuyuki.” Notwithstanding the Examiner’s conclusory assertion, the Applicants respectfully submit that Kazuyuki does not disclose or suggest each and every limitation of new claim 4 and that the “recited result” is not inherently disclosed by Kazuyuki.

Kazuyuki discloses a method of aging a plasma display panel in which a waveform of applied voltage for a discharge of an aging process has a slope portion that varies slowly, with the aim of providing of providing an image display apparatus which reduces electric power and heat generation at the time of aging processing and shows a stable discharge characteristic.

Kazuyuki does not disclose or suggest forming a discharge dent and a shape of the discharge dent, although Kazuyuki mentions that a deterioration of a fluorescent material occurs due to discharge during a period of an aging processing and an influence of an ultraviolet ray, as well as a property change of a protecting layer. In Figure 4, Kazuyuki disclose a scan electrode 102a and a sustain electrode 102b which appear to have the same or symmetrical shape.

The Examiner is requested to consider a case of aging a plasma display panel with the scan electrode 102a and the sustain electrode 102b having a symmetrical structure by applying waveforms of the applied voltages as show in Figures 1 and 4 of Kazuyuki to the scan electrode 102a and the sustain electrode 102b alternatively to each other and having the same shape, where the waveform of an applied voltage to a data electrode is flat. In such a case, both of the protecting layers on the scan electrode 102a and the sustain electrode 102b are expected to be sputtered in a similar shape. As a result, it is expected that the respective protecting layers on the scan electrode 102a and the sustain electrode 102b have similar dents formed by sputtering from the aging process.

Therefore, even if the configuration of the present invention is the same as that of Kazuyuki, Kazuyuki does not inherently disclose or suggest that a discharge dent on the protecting layer on the side of the sustain electrode, which is formed by the aging discharge, has a width which is narrower than a discharge dent on the protecting layer on the side of the scan electrode. In fact, the disclosure of Kazuyuki, for the reasons presented above, discloses the opposite, as the protective layers on the scan electrode 102a and the sustain electrode 102b of Kazuyuki will have discharge dents that are the same.

Accordingly, the Applicants respectfully submit that Kazuyuki clearly does not inherently disclose or suggest that that a discharge dent on the protecting layer on the side of the sustain electrode, which is formed by the aging discharge, has a width which is narrower than a discharge dent on the protecting layer on the side of the scan electrode, as recited in new claim 4.

Therefore, the Applicants respectfully submit that new claim 4 is clearly not anticipated by Kazuyuki since Kazuyuki fails to disclose, either inherently or explicitly, each and every limitation of new claim 4.

New claim 5 recites that, in the plasma display panel, as for a discharge dent formed on the protecting layer on the side of the sustain electrode, which is formed by the aging discharge, the discharge dent formed on the protecting layer in an area away from the scan electrode paired with the sustain electrode as the display electrode has a depth which is shallower than the discharge dent formed on the protecting layer in an area close to the scan electrode paired with the sustain electrode as the display electrode.

Similar to the reasons presented above, Kazuyuki does not disclose or suggest that a discharge dent on the protecting layer formed in an area away from the scan electrode has a depth which is shallower than the discharge dent formed on the protecting layer in an area close to the scan electrode, as recited in new claim 5. In particular, the discharge dents formed on the portions of the protecting layer over the scan electrode 102a and the sustain electrode 102b are the same. In fact, Kazuyuki provides no disclosure which would reasonably support any conclusion to the contrary.

Accordingly, similar to the reasons presented above for distinguishing new claim 4, the Applicants respectfully submit that Kazuyuki does not inherently disclose or suggest that the discharge dent formed on the protecting layer in an area away from the scan electrode paired with the sustain electrode as the display electrode has a depth which is shallower than the discharge dent formed on the protecting layer in an area close to the scan electrode paired with the sustain electrode as the display electrode, as recited in new claim 5.

Therefore, the Applicants respectfully submit that new claim 5 is clearly not anticipated by Kazuyuki since Kazuyuki fails to disclose, either inherently or explicitly, each and every limitation of new claim 5.

New claim 6 recites a method of aging a plasma display panel. New claim 6 defines that the waveform of voltage applied to the scan electrode is different in shape from the waveform of voltage applied to the sustain electrode.

In contrast to new claim 6, Figure 1 of Kazuyuki discloses that the waveforms of the voltage applied to the scan electrode 102a and the sustain electrode 102b are alternatives of each other but have the same shape. Accordingly, Kazuyuki clearly does not disclose or suggest that the waveform of voltage applied to the scan electrode is different in shape from the waveform of voltage applied to the sustain electrode, as recited in new claim 6.

Therefore, the Applicants respectfully submit that new claim 6 is clearly not anticipated by Kazuyuki since Kazuyuki fails to disclose, either inherently or explicitly, each and every limitation of new claim 6.

Because of the clear distinctions discussed above, it is submitted that the teachings of Kazuyuki clearly do not meet each and every limitation of new claims 4-6.

Furthermore, it is submitted that the clear distinctions discussed above are such that a person having ordinary skill in the art at the time the invention was made would not have been motivated to modify Kazuyuki in such a manner as to result in, or otherwise render obvious, the present invention as recited in new claims 4-6.

Therefore, it is submitted that the new claims 4-6 are clearly allowable over the prior art as applied by the Examiner.

In view of the foregoing amendments and remarks, it is respectfully submitted that the present application is clearly in condition for allowance. An early notice thereof is respectfully solicited.

If, after reviewing this Amendment, the Examiner feels there are any issues remaining which must be resolved before the application can be passed to issue, the Examiner is respectfully requested to contact the undersigned by telephone in order to resolve such issues.

A fee and a Petition for a one-month Extension of Time are filed herewith pursuant to 37 CFR § 1.136(a).

Respectfully submitted,

Masaaki YAMAUCHI et al.

DESCRIPTION

PLASMA DISPLAY PANEL AND METHOD OF AGING THE SAME

5 TECHNICAL FIELD

The present invention relates to an alternative current (AC) plasma display panel and a method of aging the same.

BACKGROUND ART

10 A plasma display panel (hereinafter referred to as a PDP or simply a panel) is a display device with an excellent visibility, and a large screen, and has a low-profile, and lightweight body. The difference in discharging divides PDPs into two types of the alternative current (AC) type and the direct current (DC) type. In terms of the structure of electrodes, the PDPs fall into the 3-electrode
15 surface discharge type and the opposing ~~discharge-discharge~~ type. In recent years, the ~~dominating~~ dominant PDP is the AC type 3-electrode surface discharge PDP by virtue of having higher resolution and easier fabrication.

Generally, the AC type 3-electrode surface discharge PDP contains a front substrate and a back substrate ~~oppositely disposed with~~ disposed opposite from
20 each other, and a plurality of discharge cells therebetween. On a front glass plate of the front substrate, scan electrodes and sustain electrodes, as display electrodes, are arranged in parallel with each other, and ~~over which~~, a dielectric layer and a protecting layer are formed over the display electrodes to cover the display electrodes. On the other hand, on a back glass plate of the back
25 substrate, data electrodes are disposed in a parallel arrangement, and ~~over which~~, a dielectric layer is formed over the data electrodes to cover the data electrodes. On the dielectric layer between the data electrodes, a plurality of

barrier ribs ~~is~~are formed in parallel with the rows of the data electrodes. Furthermore, a phosphor layer is formed between the barrier ribs and on the surface of the dielectric layer covering the data electrodes. The front substrate and the rear substrate are sealed with each other so that the display electrodes
5 are orthogonal to the data electrodes in the narrow space between the two substrates. The narrow space, i.e., ~~the~~a discharge space, is filled with a discharge gas. The panel is thus fabricated.

Such a panel ~~just finished~~fabricated in this manner, however, generally exhibits a high voltage at the start of discharging, and the discharge itself is in
10 an unstable condition. The panel is therefore aged in the manufacturing process to obtain consistent and stable discharge characteristics.

~~Conventionally, a method~~ A conventional method has been employed for aging panels in which an anti-phased rectangular wave, that is, a voltage having an alternate voltage component, is applied to a display electrode, i.e.,
15 between a scan electrode and a sustain electrode for a long period of time. ~~has been employed for aging panels.~~ To shorten the aging time, some methods have been suggested. For example, Japanese Patent Non-Examined Publication No. H07-226162 introduces ~~the~~a method in which a rectangular wave is applied, via an inductor, to the electrodes of a panel. On the other
20 hand, Japanese Patent Non-Examined Publication No. 2002-231141 suggests ~~the~~a method as a combination of two kinds of discharging. According to the method, a pulse voltage having different polarity is placed between a scan electrode and a sustain electrode (i.e., discharging in the same surface) and consecutively, a pulse voltage having different polarity is now placed between
25 the display electrodes and the data electrodes (i.e., discharging between the opposite surfaces).

Performing an aging process, as is known in the art, thins the surface of

the protecting layer due to sputtering. However, an excessively strong aging provides the surface of the protecting layer with an excessive sputtering, thereby shortening the panel life.

The present invention addresses the problem described above. It is therefore an object of the invention to provide a long-life panel with minimized aging and ~~the~~ an efficient aging method.

DISCLOSURE SUMMARY OF THE INVENTION

To achieve the object above, the present invention provides the following features. The aging process is performed on a plasma display panel having a plurality of pairs of ~~the~~ a scan electrode and ~~the~~ a sustain electrode as ~~the~~ a display electrode, a dielectric layer covering the display electrodes, and a protecting layer disposed over the dielectric layer. In the aging process, an aging discharge is performed by applying voltage having an alternate voltage component at least between the scan electrode and the sustain electrode in order to form a discharge dent on the protecting layer. According to the present invention, the aging discharge dent is formed so as to satisfy any one of the ~~followings: first~~ following. First, the discharge dent on the scan electrode-side has a width which is narrower than the discharge dent on the sustain electrode-side. ~~Secondly~~ Secondly, the discharge dent on the sustain electrode-side is ~~so~~ so formed so that the depth of the discharge dent in the area away from the scan electrode paired with the sustain electrode, as a display electrode, is shallower than the depth of the discharge dent in the area close to the counterpart scan electrode.

DETAILED DESCRIPTION OF ~~CARRYING OUT OF THE INVENTION~~

20 The exemplary embodiments of the present invention are described hereinafter with reference to the accompanying drawings.

EXEMPLARY EMBODIMENT

Fig. 1 is an exploded perspective view illustrating the structure of a panel
25 of according to an exemplary embodiment of the present invention. Panel 1 contains a front substrate 2 and a back substrate 3 in a confronting arrangement. On a front glass plate 4 of the front substrate 2, a plurality of

pairs of scan electrodes 5 and sustain electrodes 6 ~~is-are~~ arranged in parallel. The array of scan electrodes 5 and sustain electrodes 6 are covered with a dielectric layer 7, and ~~over which,~~ a protecting layer 8 is formed over the dielectric layer 7 to cover the dielectric layer 7. On the other hand, on a back glass plate 9 of the back substrate 3, a plurality of data electrodes 10 ~~is-are~~ disposed in a parallel arrangement, and ~~over which,~~ a dielectric layer 11 is formed over the data electrodes 10 to cover the data electrodes 10. On the dielectric layer 11, a plurality of barrier ribs 12 ~~is-are~~ formed in parallel with the rows of data electrodes 10. Furthermore, a phosphor layer 13 is formed between the barrier ribs 12 and on the surface of dielectric layer 11. Discharge spaces 14 formed between the front substrate 2 and the back substrate 3 are filled with a discharge gas.

Fig. 2 shows the arrangement of electrodes of the panel 1 of the embodiment. m data electrodes $10_1 - 10_m$ (corresponding to data electrodes 10 shown in Fig. 1) are arranged in a direction of ~~rows~~ columns in Fig. 2. On the other hand, in a direction of ~~columns~~ rows in Fig. 2, n scan electrodes $5_1 - 5_n$ (scan electrodes 5 of Fig. 1) and n sustain electrodes $6_1 - 6_n$ (sustain electrodes 6 of Fig. 1) are alternately disposed. The array of the electrodes above forms $m \times n$ discharge cells 18 in the discharge space. Each of the discharge cells 18 contains a pair of a scan electrode 5_i and a sustain electrode 6_i (i takes 1 to n), and one data electrode 10_j (j takes 1 to m). Scan electrode 5_i is connected to a corresponding electrode terminal section 15_i disposed around the perimeter of the panel 1. Similarly, sustain electrode 6_i is connected to a sustain electrode terminal section 16_i , and data electrode 10_j is connected to a data electrode terminal section 17_j . Here, the gap formed between the scan electrode 5 and the sustain electrode 6 for each of the discharge cells 18 is referred to as discharge gap 20, and the gap formed between the discharge cells, i.e., between

scan electrode 5_i and sustain electrode 6_{i-1} that belongs to the next (adjacent) discharge cell is referred to as an adjacent gap 21.

After completion of the aging process, the inventors disassembled a panel and observed a discharge dent (i.e., the dent formed by sputtering in the aging process). Fig. 3A schematically shows the discharge dent (the diagonally shaded areas) on the surface of the protecting layer. As shown in ~~the figure~~ Fig. 3A, on the side of the scan electrode 5, the discharge dent covers almost all over the width of the scan electrode 5, whereas on the side of the sustain electrode 6, the discharge dent localizes in the area close to the counterpart scan electrode 5 as a display electrode, that is, in the area on the side of the discharge gap 20. That is, the discharge dent formed on the side of the sustain electrode 6 is narrower in width than that formed on the side of the scan electrode 5.

The aging process provides, as described above, the surface of the protecting layer 8 with sputtering. However, the sputtering amount is very small, and the discharge dent by the aging process rarely can be found under an ordinary optical microscope. The observation of the discharge dent is done by a scanning electron microscope (SEM), which is highly sensitive to the shape of matter surface. ~~An A~~ SEM scans on the surface of a sample and finds the image of secondary electrons which are emitted from the surface. The protecting layer is formed of an MgO film. The surface of the film just ~~finished~~ fabricated has microscopic asperities that are less than 100 nm. Through the aging process, the irregular surface is smoothed by sputtering. The amount of secondary electron emission is larger from an inclined or projected surface than a flat surface. In the image of the secondary electron observed under the SEM, the well-sputtered surface of the protecting layer looks dark, whereas the surface with no sputtering or ~~not enough~~ insufficient sputtering looks bright. The discharge dent shown in Fig. 3 is observed by the SEM. Prior to

observation by the SEM, it is important that the surface of protecting layer 8 should be coated—since it is insulating material—with a thin film of platinum or gold, in order to protect the surface from being charged up.

~~Here will be described~~The following describes why the discharge dent is differently formed between the area on the side of scan electrode 5 and the area on the side of sustain electrode 6.

In a sequence of initial, writing, and sustaining discharge of the 3-electrode PDP in operation, the writing discharge and the sustaining discharge are under the influence of the operating voltage. Fig. 3B schematically shows the discharge dent which is essential to lower and stabilize the voltage at the start of the sustaining discharge. In the sustaining discharge, the discharge occurs by applying a rectangular voltage pulse between the scan electrode 5 and the sustain electrode 6. At this time, the discharge occurs in the areas close to the discharge gap 20 of the ~~two scan and sustain~~ electrodes 5,6. The areas ~~are required~~require to having enough aging, i.e., the surfaces of the protecting layer in the areas have to be well sputtered; otherwise, the surfaces of the areas would undergo sputtering in the sustaining discharge in the panel operation, as well as in the aging process, and the shape of the surfaces is altered by the undesired sputtering. The change in shape of the surface invites variations in voltage of the sustaining discharge, resulting in poor display characteristics. To protect the panel from the above inconveniencies~~above~~, the aging process should be performed so as to focus on the area close to discharge gap 20 in the scan electrode 5 and the sustain electrode 6. Compared to the discharge dent of the area on the side of adjacent gap 21, the discharge dent of the area on the side of discharge gap 20 has to have an enough depth so as to minimize the change in shape of the surface of the protecting layer in the panel operations. In other words, for obtaining the

stability of the sustaining discharge, the area on the side of adjacent gap 21 is does not necessarily ~~to~~ have a deep discharge dent by a strong aging.

On the other hand, Fig. 3C schematically shows the discharge dent which is essential to lower and stabilize the voltage at the start of the writing discharge. The writing discharge occurs between the scan electrode 5 and the data electrode 10. To obtain stability of voltage in the writing discharge in panel operation, it is preferable that the entire area on the side of the scan electrode 5 facing the data electrode 10 undergoes aging so as to have uniform discharge dent by entire sputtering. That is, as far as the writing discharge is concerned, the aging on the side of the sustaining electrode 6, i.e., forming the discharge dent on that side ~~has~~ does not have much importance.

Therefore, in order to stabilize both of the sustaining, and writing discharges, the aging should preferably be performed on the area that covers both the diagonally shaded areas in Figs. 3B and 3C—, i.e., the area shown in Fig. 3A. Although the area on the side of the discharge gap 20 of the scan electrode 5 undergoes both the sustaining discharge and the writing discharge, ~~the~~ this area ~~has not~~ does not need to have a discharge dent which is deeper than the area on the side of the adjacent gap 21 of an identical scan electrode 5. The aging should be uniformly performed on the entire area on the side of the scan electrode 5. On the contrary, an excessive aging on the area on the side of the discharge gap 20 not only shortens the life of a panel, but also increases unnecessary electric power.

Fig. 3D schematically shows a depth distribution of the discharge dent formed on the panel of the embodiment. According to the aging of the embodiment, the discharge dent is formed so as to have a distribution with continuous and gradual change shown in Fig. 3D, instead of a “two-valued” distribution shown in Fig. 3A. The discharge dent on the side of the sustain

electrode 6 is so-formed so that the depth of the discharge dent in the area away from the scan electrode 5 paired with the sustain electrode 6 as the counterpart of a display electrode is shallower than the depth in the area close to the counterpart scan electrode 5.

5 As described above, performing a minimum amount of aging on a necessary area can minimize sputtering to the protecting layer 8, thereby increasing the life of the panel. ~~As~~An additional ~~plus~~advantage is that the aging time can be shortened, with the efficiency of electric power increased.

10 Figs. 4A and 4B show examples of aging waveforms to form an asymmetric discharge dent of the embodiment. As shown in ~~the figures~~Figs. 4A and 4B, a voltage having an alternate voltage component is applied between the scan electrode 5 and the sustain electrode 6. The voltage applied to the scan electrode 5 exhibits, as shown in Fig. 4A, a leading edge having a mild slope and a precipitous trailing edge. In contrast, the voltage applied to the sustain electrode 6 has a precipitous leading edge and a mild trailing edge, as
15 shown in Fig. 4B. Although the leading edge of the voltage waveform for the scan electrode 5 and the trailing edge of the waveform for the sustain electrode 6 have a mild slope in the embodiment, ~~it~~the present invention is not limited thereto; either one of them may exhibit a mild slope. The voltage waveform
20 applied to the data electrode 10 is not shown in ~~the figure~~Figs. 4A and 4B. Data electrode 10 may be placed with no voltage, or may be connected to a ground.

25 Fig. 4C schematically shows light emission of a panel in the form of a waveform detected by a photo sensor according to the embodiment. As is apparent from ~~the figure~~Fig. 4C, a strong discharge occurs in response to a steep change in voltage and a weak discharge occurs at a mild change in voltage. In the aging waveform, when the strong discharge occurs, positive ions

attracted to the scan electrode 5 as the cathode cause a strong sputtering on the surface of the protecting layer 8. On the other hand, the sustain electrode 6 collects electrons; however, an electron has small mass. Therefore, a strong sputtering never occurs on the surface on the side of the sustain electrode 6.

5 The weak discharge following the strong discharge is the discharge that is localized around the discharge gap 20. In the discharge, positive ions, which are attracted to the sustain electrode 6 close to the discharge gap 20, cause a strong sputtering on the surface of the protecting layer 8. The repeatedly caused sputtering is believed to be forming the discharge dent shown in Fig. 3A.

10 As described above, by generating a relatively strong discharge when the voltage waveform applied to scan electrode 5 has the trailing edge (i.e., when the scan electrode 5 acts as cathode); on the other hand, generating a relatively weak discharge when the voltage waveform applied to the sustain electrode 6 has the trailing edge (i.e., when the sustain electrode 6 acts as cathode), the

15 discharge dent shown in Fig. 3 can be formed. However, an excessively strong discharge, which is brought by an application of increased voltage to the electrodes, is not desired in the aging process. Through such a too strong discharge, the depth of the discharge dent on the side of the adjacent gap 21 is inconveniently deeper than that of the discharge dent on the side of the

20 discharge gap 20. According to the embodiment of the present invention, the optimum voltage is experimentally determined ~~at~~ to be 210V. The optimum voltage highly depends on the electrode structure and the material of a panel; the voltage value should be optimized to each panel.

Prior to the actual panel operation, a panel has to undergo the aging

25 process so as to operate with stability in the sustaining discharge and the writing discharge—two main discharges in an AC type 3-electrode PDP. According to the embodiment, a desired discharge dent, as shown in Fig. 3A,

can be formed on the surface of the protecting layer 8 by performing a minimized aging. Conversely, designing the aging waveform and aging device so as to form the discharge dent of Fig. 3A allows a panel to have a long life.

The plasma display panel of the present invention has a long operating
5 life by virtue of a minimized discharge dent.

INDUSTRIAL APPLICABILITY

The present invention introduces a panel having a minimal amount of discharge dent and an aging method of forming the minimized discharge dent
10 on a panel. The method is effective in aging an AC type plasma display panel, and the panel processed by the method provides a long lasting quality.

ABSTRACT

In the ~~an~~ aging process in which a voltage having an alternate voltage component is applied to at least between a scan electrode (5) and a sustain electrode (6) so as to form a discharge dent (sputter dent) on the ~~a~~ protecting layer, the aging discharge dent is formed so as to satisfy any one of the followingsfollowing. Firstly~~First~~, the discharge dent on the scan electrode-side has a width which is narrower than the discharge dent on the side of sustain electrode (6). Secondly~~Second~~, the discharge dent on the side of sustain electrode (6) is formed so that the depth of the discharge dent in the area away from a scan electrode (5) paired with a sustain electrode (6) as a display electrode is shallower than the depth of the discharge dent in the area close to counterpart scan electrode (5).
